

To do computation, we must first convert from first-order logic to propositional logic.  
 In general, we do replacement, written as:  $\{x/y\}$  — replace x with y.  
 We must handle instantiation uniquely, however:

1. UNIVERSAL INSTANTIATION  
 $(\forall \text{ variable}) (\text{sentence}) \text{ subst}(\text{variable/ground-term}, \text{sentence})$   
 ex: for constants {John, Richard}:  
 $\forall x \text{ King}(x) \wedge \text{Greedy}(x) \implies \text{Evil}(x)$   
 $\rightarrow \text{King}(\text{John}) \wedge \text{Greedy}(\text{John}) \implies \text{Evil}(\text{John})$   
 $\rightarrow \text{King}(\text{Richard}) \wedge \text{Greedy}(\text{Richard}) \implies \text{Evil}(\text{Richard})$   
 $\rightarrow \text{King}(\text{Father}(\text{John})) \wedge \text{Greedy}(\text{Father}(\text{John})) \implies \text{Evil}(\text{Father}(\text{John}))$   
 While this creates ground sentences, we can see that it could run infinitely
2. EXISTENTIAL INSTANTIATION  
 $(\exists \text{ variable}) (\text{sentence}) \text{ subst}(\text{variable/new-constant}, \text{sentence})$   
 ex: for constants {C}  
 $\exists x \text{ Crown}(x) \wedge \text{On-Head}(x, \text{John})$   
 $\rightarrow \text{Crown}(C) \wedge \text{On-Head}(C, \text{John})$

Without any functions, this term count is finite, but with functions, it could be infinite.  
 We can see that in these cases:

1.  $\forall \text{ level } 1 = \forall \text{ level } 2$
2.  $\text{SAT}(\exists \text{ level } 1) \iff \text{SAT}(\exists \text{ level } 2)$

This has a major result:

**Theorem (Herbrand 1980)**

if a sentence is entailed by a first order logic knowledge base,  
 then it is entailed by a finite subset of that propositional knowledge base.

Application:

for  $n = 0$  to  $\infty$  do  
     create a propositional knowledge base by instantiating with depth-n terms  
     see if the sentence is entailed by this knowledge base

We have a problem, however:

this only terminates if the sentence is entailed!  
 $\implies$  inference is considered **semi-decidable** (Church/Turing 1936)

We can use resolution to prove implications as with propositional logic.

We must first define the idea of **unification**.

A **unifier** is a set of variable assignments that make two statements equivalent.

Examples:

1.  $\text{Knows}(\text{John}, x) \wedge \text{Knows}(\text{John}, \text{John}), \{x/\text{John}\} \rightarrow \text{Knows}(\text{John}, \text{John})$
2.  $\text{Knows}(\text{John}, x) \wedge \text{Knows}(y, \text{OJ}), \{x/\text{OJ}, y/\text{John}\} \rightarrow \text{Knows}(\text{John}, \text{OJ})$
3.  $\text{Knows}(\text{John}, x) \wedge \text{Knows}(y, \text{Mother}(y)), \{x/\text{Mother}(\text{John}), y/\text{John}\} \rightarrow \text{Knows}(\text{John}, \text{Mother}(\text{John}))$
4.  $\text{Knows}(\text{John}, x) \wedge \text{Knows}(x, \text{OJ}), \text{NO SOLUTION}$

We can improve unification by indexing facts/predicate indexing

$\equiv$  we cache highly used facts — very useful for many predicate, few clause logics.

If we store by predicate and first argument, then we can lookup by either.

This formed a subsumption lattice where children are formed by substitution on a higher.

In this lattice, the highest common descendent of two nodes comes from their MGU.

Since this is  $O(2^n)$ , it requires a small n; thankfully, most AI problems meet this.

First order resolution goes as in the following example:

$(\forall x \text{ Rich}(x) \implies \text{Unhappy}(x)), \text{Rich}(\text{Ken}))$   
 $\{\neg \text{Rich}(x) \vee \text{Unhappy}(x), \text{Rich}(\text{Ken})\}$   
 $\neg \text{Rich}(x) \vee \frac{\text{Unhappy}(x), \text{Rich}(\text{Ken})}{\text{Unhappy}(\text{Ken})} \text{ with } \{x/\text{Ken}\}$

We use this to walk through the following proof:

Statements:

- Jack owns a dog.
- Every dog owner is an animal lover
- No animal lover kills an animal

- Either Jack or curiosity killed the cat
- Cats are animals

Query: Did curiosity kill the cat?

First Order Knowledge Base:

- Owns(Jack, Dog)
- $\forall x (exists\ y\ Owns(x, y) \wedge Dog(y)) \implies ALover(x)$
- $\forall x ALover(x) \implies (\forall y Animal(y) \implies \neg kills(x, y))$
- Kills(Jack, Tuna)  $\vee$  Kills(Curiosity, Tuna)
- Cat(Tuna)
- $\forall x Cat(x) \implies Animal(x)$

CNF Knowledge Base:

1. Dog(D)
  2. Owns(Jack, D)
  3.  $\neg Owns(x, y) \vee \neg Dog(y) \vee ALover(x)$
  4.  $\neg ALover(x) \vee \neg Animal(y) \vee \neg Kills(x, y)$
  5. Kills(Jack, Tuna)  $\vee$  Kills(Curiosity, Tuna)
  6. Cat(Tuna)
  7.  $\neg Cat(x) \vee Animal(x)$
  8. Query —  $\neg Kills(Curiosity, Tuna)$
- 
9.  $\neg Owns(x, D) \vee ALover(x)$  by <1, 5>: y/D
  10. ALover(Jack) by <2, 9>: x/Jack
  11. Animal(Tuna) by <7, 8>: x/Tuna
  12.  $\neg ALover(x) \vee \neg Kills(x, Tuna)$  by <4, 11>: x/Tuna
  13.  $\neg Kills(Jack, Tuna)$  by <10, 12>: x/Jack
  14. Kills(Jack, Tuna) by <8, 5>
  15. CONTRADICTION by <12, 13>

To perform resolution, we need a CNF; we convert to a CNF much the same as with propositional:

Consider:  $\forall x [\forall y Animal(y) \implies Loves(x, y)] \implies [\exists y Loves(y, x)]$

Step 1: eliminate  $\implies$  and  $\iff$

$$\forall x [\neg \forall y \neg Animal(y) \vee Loves(x, y)] \vee [\exists y Loves(y, x)]$$

Step 2: move negation inward

$$\forall x [\exists y Animal(y) \wedge \neg Loves(x, y)] \vee [\exists y Loves(y, x)]$$

Step 3: standardize variables

$$\forall x [\exists y Animal(y) \wedge \neg Loves(x, y)] \vee [\exists z Loves(z, x)]$$

Step 4: “skolem”-ize

$$\forall x [Animal(F(x)) \wedge \neg Loves(x, F(x))] \vee [Loves(G(x), x)]$$

Step 5: drop universal quantifiers

$$[Animal(F(x)) \wedge \neg Loves(x, F(x))] \vee [Loves(G(x), x)]$$

Step 6: distribute

$$[Animal(F(x)) \vee Loves(G(x), x)] \vee [\neg Loves(x, F(x)) \vee Loves(G(x), x)]$$

We have a special case when the knowledge base contains only **definite clauses**.

a definite clause contains exactly one positive term (ex  $\neg A \vee \neg B \vee C$ )

we can thus convert these to an if-then rule (ex  $A \wedge B \implies C$ )

We will show two special algorithms for dealing with definite clause knowledge bases.

We will do this with the following example:

1. American(x)  $\wedge$  Weapon(x)  $\wedge$  Sells(x, y, z)  $\wedge$  Hostile(z)  $\implies$  Criminal(x)
2.  $\exists x Owns(Nono, x) \wedge Missile(x)$   
Owns(Nono, M1)  $\wedge$  Missile(M1)
3. Missile(x)  $\wedge$  Owns(Nono, x)  $\implies$  sells(West, x, Nono)
4. Missile(x)  $\implies$  Weapon(x)
5. Enemy(x, America)  $\implies$  Hostile(x)

6. American(West)

7. Enemy(Nono, America)

Notice that to be operated on, all clauses must be universally quantified

### **Forward Chaining**

If there are no function symbols and all clauses are definite, the KB is a **data log**

These are especially conducive to representing databases.

If we preprocess as rules come in, we can handle many facts and even model a brain in real time.

### **Backward Chaining**

This is often used with improvements for logic programming (as in prolog)  
The system often caches subgoals (like `Missile(y)`) for efficiency's sake
